Project Title	PathForge
Project Description	PathForge is a project management tool that helps users set long-term goals, break big tasks into smaller ones, and track progress through completion. Unlike traditional to-do lists, PathForge requires users to map out relationships between tasks, creating a clear roadmap from start to finish. It combines long-term planning with daily task tracking, helping users maintain momentum toward their goals. Core Functionality: 1. Users begin by defining a high-level goal and inputting the tasks they need to complete. 2. Users can drag and drop to create dependency connections between tasks, building a directed graph and timeline that shows which tasks need to be completed and in what order. 3. The interface distinguishes between available tasks and those blocked by incomplete prerequisites. Example Use Cases:

1. Consider someone aiming to reach B1 German proficiency in 9 months. They know their tasks: complete the A1, A2, and B1 courses, build a 3000-word vocabulary, work through B1 exam materials, and take the B1 certification. PathForge helps them map these linear dependencies and track daily progress on recurring activities like Duolingo lessons, German podcasts, and reading exercises. As they complete the A1 course, PathForge highlights that the A2 phase is now unlocked and ready to begin.
2. Someone pursuing a tech job might have parallel paths: building portfolio projects, earning certifications, refining their resume, practicing coding challenges, networking, preparing for interviews, applying to internships, and ultimately applying to full-time positions. PathForge reveals which tasks can be worked on simultaneously and which have prerequisites—for instance, interview preparation can happen alongside portfolio building, but applying to jobs requires a completed resume first.

Interactive Features

1. PathForge automatically unlocks dependent tasks as users complete current tasks.
2. Users can interact with a timeline slider to adjust task durations

	and see how changes affect their entire project plan. 3. Dynamic filtering allows users to view only blocked tasks, available tasks, or the critical path (the sequence of tasks that determines the project completion time). 4. The reflection feature creates a meaningful record that transforms task completion into a narrative of growth. When completing a phase, users can summarize what they accomplished, reflect on their experience through diary-style entries (challenges faced, lessons learned, and personal growth), and make wishes or set intentions for the next phase. For example, after passing a tech interview, a user might reflect: "Coding was harder than expected, but daily practice on LeetCode made a difference," and wish: "I can do better on behavior questions for the next interview."
